

Figure 1. Physical Photo of ATLS1A103S

FEATURES

- Ultra Low Noise: $6\mu A_{p-p}$ @0.1Hz to 10Hz
- High Output Current: 1A
- High Absolute Accuracy: $\pm 0.2\%$
- High Stability: $<100ppm/^{\circ}C$
- Programmable Current Limit
- Complete Shielding
- Compact Size
- 100 % Lead (Pb)-free and RoHS Compliant
- DIP and SMT Packages Available

APPLICATIONS

Driving laser diodes with low noise, including DPSSL, EDFA, SOA, fiber laser, direct diode lasers, etc.

DESCRIPTION

The ATLS1A103 is an electronic module designed for driving diode lasers with up to 1A low noise current. Figure 1 shows physical photo of ATLS1A103. The output voltage is 0.4V to $V_{VPS} - 1V$ when powered by a 5V power supply.

When the maximum power consumed by the controller is maintained to $<1W$, it does not require a heat sink to operate. The controller has temperature compensation network so that the output current maintains the same even as the controller temperature rises.

Table 1. Pin Function Descriptions

Pin #	Pin Name	Pin Type	Description
1	SDN	Digital input	For ATLS1A103: Shut down control. Negative logic. For ATLS1A103-PD: Shut down control. Positive logic. There is a pull-down resistor of 100k to the ground. When this pin is left unconnected, it is pulled high, 4.6V.
2	GND	Signal ground	Signal ground pin. Connect ADC and DAC grounds to here.

In case the controller temperature exceeds a preset limit, $120^{\circ}C$, the controller will be shut down by itself to prevent the controller from being damaged by the over heat.

The output current of the ATLS1A103 can be set by an input voltage linearly or modulated by an external large signal of up to 1MHz in bandwidth, resulting in a minimum 170nS rise and fall time (Large signal) at the output current.

A highly stable low noise 2.5V reference voltage is provided internally for setting the output current. This reference can also be used as the voltage reference for external ADCs (Analog to Digital Converters) and/or DACs (Digital to Analog Converters) which are utilized for converting the analog signals, such as LIO which represents the output current, into digital signals, and/or converting the digital signals into analog ones for setting the analog voltages, such as LIS which sets the output current.

The ATLS1A103 is packaged in a 6 sided metal enclosure, which blocks EMIs (Electro-Magnetic Interferences) to prevent the controller and other electronics from interfering each other.

This laser driver can be evaluated by our evaluation board, [ATLS1A103DEV1.0](#).

There are 2 packaging versions available: DIP through hole package and surface mount type.

Warning: Both the surface mount and the through hole types of modules can only be soldered manually on the board by a solder iron of $< 310^{\circ}C$ ($590^{\circ}F$), not go through a reflow oven process.

Figure 2. Pin Names and Locations

Figure 2 is the actual size top view of the ATLS1A103, which shows the pin names and locations. Its thickness is 5mm. Table 1 shows the pin function descriptions.

3	2.5VR	Analog output	2.5V reference voltage. It is used by the internal DACs as the reference voltage. It can source 3mA max, with $5\mu\text{V}_{\text{P-P}}$ noise @ 0.1Hz to 10Hz and 25ppm/°C stability max.
4	LILM	Analog input	Laser current limit set. 0V to 2.5V sets the laser current limit from 0 to 1.1A linearly.
5	LIS	Analog input	Laser current set. 0V to 2.5V sets the laser current from 0 to 1A linearly.
6	LIO	Analog output	Laser current output indication. 0V to 2.5V indicates the laser current from 0A to 1A linearly.
7	LPGD	Digital output	Loop good indication. When the controller is working properly, this pin is pulled high. Otherwise, it is pulled low.
8	TMPO	Analog output	The driver internal temperature indication output. Operating internally temperature.
9	LDA	Analog output	Laser diode anode. Connect it to the anode of the laser diode. This pin is used to drive a laser of which the cathode is connected to the case and the case is connected to the ground. Make sure $V_{\text{LDA}} > 0.8\text{V}$. See below Figure 4 or Figure 7.
10	LDC	Power ground	Laser diode cathode. Only connect to the cathode of the laser diode. See below Figure 4 or Figure 7.
11	PGND	Power ground	Power ground pin. Connect it directly to power supply return rail.
12	VPS	Power input	Power supply. The driver works from 3.8V to 5.5V.

SPECIFICATIONS

Table 2. Characteristics ($T_{\text{ambient}} = 25^\circ\text{C}$)

Parameter	Value	Unit/Note
Maximum output current	1	A
Output current noise (0.1Hz to 10Hz)	6	$\mu\text{A}_{\text{P-P}}$
Current set voltage range	0 ~ 2.5	V
Current limit set voltage range	0 ~ 2.5	V
Minimum drop out voltage	1.2V@ $V_{\text{VPS}}=3.1\text{V}$	V
	0.8V@ $V_{\text{VPS}}=5.5\text{V}$	
Power supply voltage range	3.8 ~ 5.5	V
Operating case temperature	-40 ~ 85	°C
Bandwidth of large signal	1	MHz
Bandwidth of small signal	1.2	MHz
Rise and fall times of small signal	300	nS
Rise and fall times of large signal	170	nS

OPERATION PRINCIPLE

The block diagram of the controller is shown in Figure 3.

The shut down control circuit is activated under one of these 3 circumstances: external shut down, output current exceeds the current limit, and the internal temperature exceeds 120°C.

When the controller is shut down by the external shutdown signal, it will restart upon detecting the releasing of the shutdown signal.

When it is shut down by the over current limit, the controller shuts down itself and restarts again by going through the soft-start process immediately. Therefore, the output current has a saw-tooth waveform: quick shut down, slow and ramp up.

When the controller is shut down by the over temperature, it will wait till the temperature goes below the temperature limit, 120°C. Usually it takes a few or tens of seconds for the controller to cool down before it restarts itself, depending on the thermal mass of the controller and its surrounding mechanical parts attached thermally, such as the PCB and its traces, the heat-sinks if any, etc.

When controller is shut down, the voltage reference is also shut down.

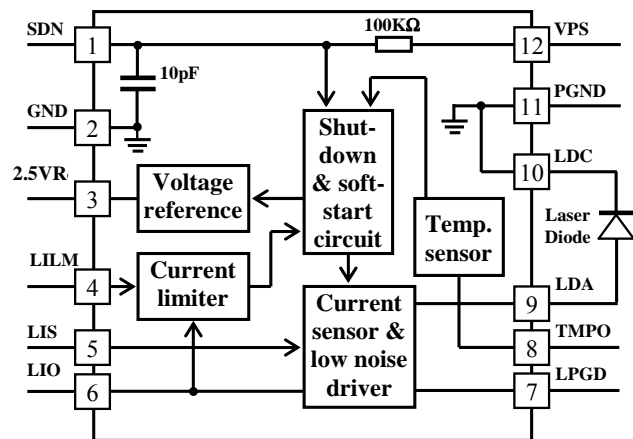

Figure 3. Block Diagram

Note: The Pin 7, LPGD, is pulled down by an open drain MOSFET and pulled up by a 5k resistor tied to VPS rail.

APPLICATIONS

Figure 4.1 and 4.2 show a typical application circuit. W1 and W2 set the output current limit and output current respectively. Resistor R1 and capacitor C1 form a low pass filter, to lower the noise from the voltage reference.

Laser diode D1 is connected between LDA and LDC. It is worth mentioning that the power supply return terminal should be connected to the pin 11 PGND and the cathode of the laser diode should be connected to the pin 10 LDC. These 2 nodes should not be connected together externally and they are connected together internally already by the controller.

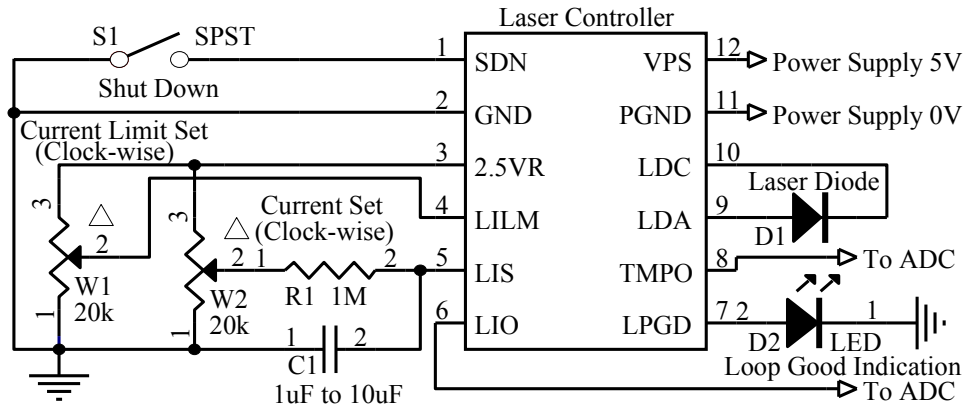

Figure 4.1. Typical Stand-alone CW Operation Schematic for ATLS1A103

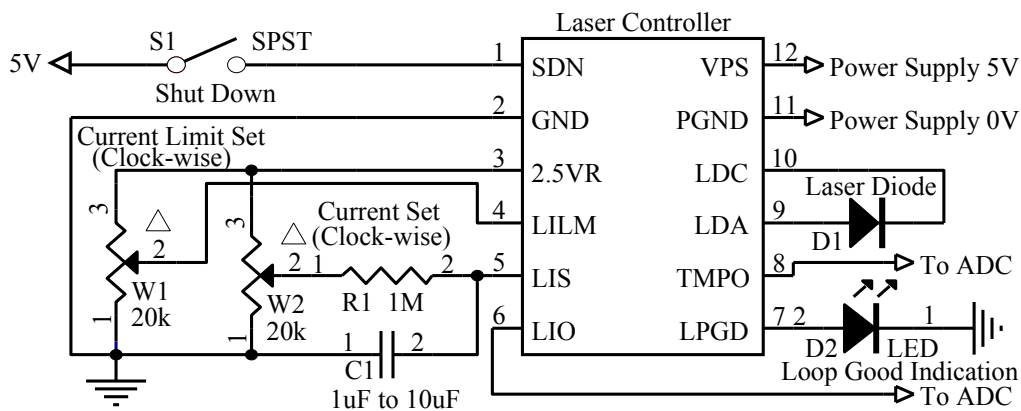

Figure 4.2. Typical Stand-alone CW Operation Schematic for ATLS1A103-PD

Turning the Controller On and Off

The controller can be turned on and off by setting the SDN pin high and lower respectively. It is recommended to turn the controller on by this sequence:

To turn on: For ATLS1A103, turn on the power by providing the power supply voltage to the controller, turn on the controller by releasing the SDN pin. For ATLS1A103-PD, turn on the power by providing the power supply voltage to the controller, turn on the controller by connecting the SDN pin to VPS.

To turn off: turn off the controller by lowering the voltage of SDN pin, turn off the power by stopping the voltage supply on the VPS pin.

In Figure 4.1 and 4.2, S1 is the shut down switch. For ATLS1A103, the internal equivalent input circuit of SDN pin is a pull-up resistor of 100k being connected to VPS in

parallel with a 10pF capacitor to the ground. For ATLS1A103-PD, the internal equivalent input circuit of SDN pin is a pull-down resistor of 100k being connected to the ground in parallel with a 10pF capacitor to the ground. The switch S1 can also be an electronic switch, such as an I/O pin of a micro-controller, with an either open drain or push/pull output. If not using a switch (S1) to control the laser, leave the SDN pin unconnected. D2 is an LED, indicating when the control loop works properly, that is: the output current equals to the input set value. Pin LPGD has an internal pull up resistor of 5k to the power supply pin, VPS, pin 10. The pull down resistance is 200Ω. This 5k resistor can drive a high efficiency LED directly. When higher pull up current is needed for driving such as a higher current LED, an external resistor can be placed between the VPS and the LPGD pins. Make sure that the resistor is not too small that the pull down resistor will not be able to pull the pin low enough when the controller loop is not good. When choosing not to use an LED for indicating the working status, leave the

LPGD pin unconnected.

The LPGD pin can also be connected to a digital input pin of a micro-controller, when software/firmware is utilized in the system.

Setting the Output Current

Figure 5. V_{LIO} & I_{OUT}

Figure 5 shows the relationship between V_{LIO} and the output current. When V_{LIO} is 0.1V, the laser driver starts to output the current, 4mA. The condition is $V_{LDA} > 1.2V$.

The output current limit is set by adjusting W1, which sets input voltages of LILM, pin 4. The output current limit will be:

$$I_{OUT} (A) = 1.1 (A) \times V_{LILM} (V) / 2.5 (V).$$

LILM should never be left float. Otherwise, the output current limit may be set to too high a value that the laser might be damaged by an excessive current.

The output current is set by adjusting W2, which sets input voltages of LIS, pin 5. The output current will be:

$$I_{OUT} (A) = 1 (A) \times V_{LIS} (V) / 2.5 (V).$$

When no modulation is needed, it is suggested to use an RC low-pass-filter, the R1 and C1 in Figure 4.1, to lower the AC noise from the voltage reference source. The time constant of this filter can be between a few to 10's of seconds. The larger the time constant, the lower the output noise, but the longer time will be needed to wait for the output current to go up.

Both of LILM and LIS can be configured by using DACs, to replace the W1 and W2 in Figure 4.1. Make sure that the DACs have low output noise, or, if no modulation is needed, an RC low pass filter can be inserted between the DAC and the LIS pin, similar as shown in Figure 4.1, to reduce the output current noise caused by the DAC's noise.

The LIS allows modulating the output current by a large signal of up to 1MHz in bandwidth. That is, when using a sine wave signal to modulate the LIS pin, the modulated AC component in the output current will be attenuated by 3dB

in magnitude, or 0.71 times of the full response magnitude. When using an ideal square-wave to modulate the output current at the LIS pin, the rise and fall time of the output current will be about 170ns (Large signal).

When the modulation signal is a square-wave and low output noise is required, the low-pass-filter can still be used for lowering the output noise. Figure 7 shows such a circuit. A digital signal is applied to the control input of an analog switch. As the control signal is at logic low, the switch is placed to NC (Normally Closed) pin, the voltage V_{LISL} is applied to the LIS pin of the controller. The output current is now set by the V_{LISL} voltage which is determined by the ratio of R2 and R3 by this formula:

$$V_{LISL} = 2.5V \times R3 / (R2 + R3).$$

Make sure to set the LISL voltage low enough so that the output current set by this voltage is lower than the laser's threshold current, thus, there is no laser beam emitted under this current. As the digital control signal is at logic high, the analog switch is placed to the NO (Normally Open) pin, the output current is now set by the V_{LISH} voltage, which is determined by the W2. The reason to modulate the laser current in the non-zero valley current way is to avoid current distortions at the output and increase output modulation speed. The detail explanation is given in the next section.

It is recommended not to set the LIS pin to 0V, but keep it $> 0.05V$ at all the time. The reason is that the laser diode usually has a junction voltage of 2.5V, when setting the LIS pin voltage to 0V, the output voltage will warble between 0V and 2.5V, causing oscillations slightly.

The LIO can still be used to monitor the output current when the LIS is modulated. The bandwidth of the LIO signal is $> 10MHz$, more than enough for monitoring output current modulated by the LIS signal.

Figure 6. V_{VPS} vs. V_{LDA}

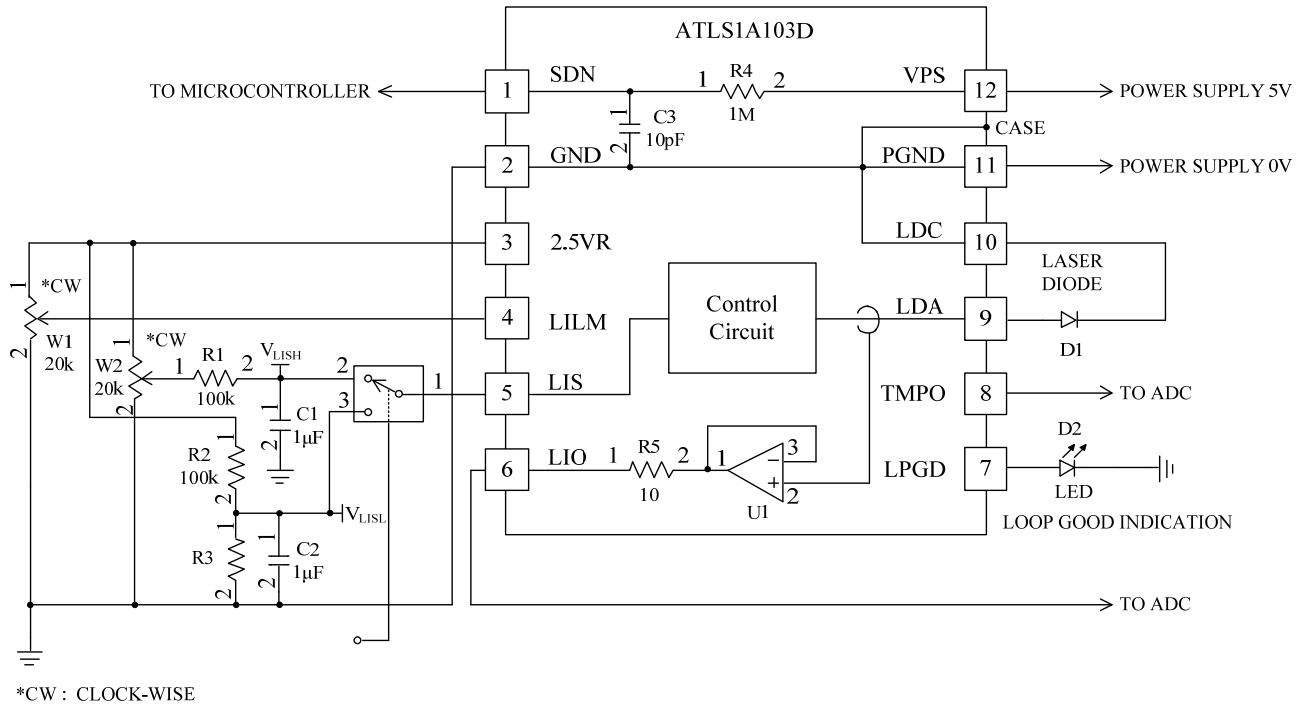

Figure 7. Low Noise Digital Modulation Circuit

Note:

- V_{VPS} : the power supply voltage on VPS pin
- V_{LDAMAX} : the maximum output voltage of LDA pin
- V_{LD} : the forward voltage of the laser diode
- V_{LDH} : the highest forward voltage of the laser diode on the modulation
- V_{LDL} : the lowest voltage of the laser diode on the modulation
- V_{LIOH} : the highest voltage of LIO pin
- V_{LIOl} : the lowest voltage of LIO pin
- P_{OLD} : the optical output power of the laser diode
- P_{OLDH} : the highest optical output power of the laser diode on the modulation
- I_{LD} : the laser diode current
- I_{LDH} : the highest laser diode current on the modulation
- I_{LDL} : the lowest laser diode current on the modulation

Figure 8. Power Supply Voltage V_{VPS} vs. LDA Pin Maximum Voltage V_{LDAMAX}

Maximum LDA Output Voltage vs. Power Supply Voltage

The maximum LDA pin output voltage is depending on the power supply input voltage, V_{VPS} . Their relationship is shown in Figure 8. Therefore, it is recommended that:

$$V_{VPS} \geq V_{LDAMAX} + 1V,$$

Where V_{LDAMAX} is the laser diode’s maximum possible forward voltage at the operation current.

To Avoid Output Current Distortions

The laser diode's forward voltage and current has a non-linear relationship shown in Figure 9.1 and 9.2. It can be seen that when the current is low, the voltage is uncertain, it can be between 0V to 1V or more. Thus, when setting the output current to zero, the output voltage will oscillate between 0V to about 1V or 1.5V, depending on the wavelength of the laser diode. If we set the lowest output current to a non-zero value, such as 1/10 of the laser's operating current but lower than the laser's threshold current, the laser's optical beam can still be cut-off, but the output voltage will not oscillate, thus the output current will not have distortions. The status of the LIO is similar as the Figure 10 shown without output current distortions.

Figure 9.1. Laser Diode Current I_LD vs. Laser Diode Voltage V_LD

Figure 9.2. Laser Diode Voltage v_LD(t) Waveform

Figure 10. LIO Pin Voltage v_LIO(t) Waveform

The laser's threshold current is shown in Figure 11. It can be seen that when the laser's current fall below a certain value, there is no output optical power. For example, the operating current and threshold current of a red laser diode of 650nm are 30mA and 20mA respectively and the optical output power is 4mW. It will have no optical output power if the output current of this laser diode is lower than 20mA which is its threshold current. Figure 12 and Figure 13 will describe you the relationship between the I_LD and P_LD.

Figure 11. Laser Diode Current I_LD vs. Laser Diode Optical Power P_OLD

Figure 12. Laser Diode Current i_LD Waveform

Figure 13. Laser Diode Optical Power p_OLD Waveform

Monitoring the Output Current

The output current of the controller can be monitored by measuring the voltage on the LIO pin. This feature is very useful for micro-controller based system where the ADC is available and monitoring the current in real time is required. This pin provides a very low noise voltage signal which is proportional to the output current:

$$V_{LIO} (V) = I_{OUT} \times 2.5 (V).$$

For example, when the output signal equals to 2.5V, the output current is 1A.

The output impedance of this pin is 10Ω and it can be used to drive an ADC directly.

It can also be measured by a multimeter during debugging process.

Figure 14 below shows the relations among V_{LIS} , V_{LIMS} and I_{OUT}

Figure 14. V_{LIS} & V_{LIO}

When $V_{LIS} \leq V_{LIMS}$, I_{OUT} changes with V_{LIS} linearly; when $V_{LIS} > V_{LIMS}$, I_{OUT} oscillates between 0 and V_{LIMS} .

Monitoring the Controller Internal Temperature

The controller internal temperature can be monitored by measuring the TMPO pin voltage. The relationship between the TMPO voltage and the temperature is:

$$T = -1525.04 + 10^3 \sqrt{2.4182 + \frac{1.8015 - TMPO}{3.479}} (^{\circ}C) \quad (1)$$

where TMPO is the voltage on the TMPO pin.

This formula can be approximated by a linear equation:

$$T = 192.7 - 90.31 \times TMPO (^{\circ}C) \quad (2)$$

Within the most commonly used temperature range of between 0°C to 100°C, the maximum error occurs at about 1.5V, at which the temperature error between the calculated data by using the formula (1) and the approximated data obtained by using the linear equation (2) is about 0.4°C, with

the linear data being a little lower. The curves of the 2 sets of the data are plotted in Figure 18.

Please notice that the TMPO pin has a weak driving capability: the maximum sourcing current is 1μA and the maximum sinking current is 40μA.

The TMPO pin can also be used as an input control pin: when forcing the TMPO voltage to below 0.4V, the laser controller will be shutdown.

First Time Power Up

Laser is a high value and vulnerable device. Faults in connections and damages done to the controller during soldering process may damage the laser permanently.

To protect the laser, it is highly recommend to use 3 to 4 regular diodes of >500mA to form a “dummy laser” and insert it in the place of the real laser diode, when powering up the controller for the first time. Use an oscilloscope to monitor the LDA voltage at times of power-up and power-down, make sure that there is no over-shoot in voltage. At the same time, use an ammeter in series with the dummy laser, to make sure that the output current is correct.

After thorough checking free of faults, disconnect the dummy laser and connect the real laser in place.

The controller output voltage range for the laser is between 0.4V to $V_{VPS} - 1V$ when powered by a 5V power supply.

Controller Power Consumption

The power consumption of the controller can be calculated by:

$$P_{DRIVER} = I_{OUT} \times (V_{VPS} - V_{LDA}),$$

where I_{OUT} is the output current;

V_{VPS} is the power supply voltage;

V_{LDA} is the voltage across the laser diode.

When the P_{DRIVER} exceeds 1W, a heat sink might be needed. The best way for arranging the heat sinking for the driver is as follows: transferring the heat by sandwiching a piece of thermal conductive pad between the top metal surface of the laser driver and the internal metal surface of the final product as shown in Figure 15.1 and 15.2 below. The recommended thickness of the thermal conductive pad in Figure 15.1 is 1~4mm, and in Figure 15.2 is 0.5mm. ATI also provides a series of thermal conductive pads, click [here](#) for more information.

If prefer not to use the heat sink, this is an option: lowering the controller power consumption by reducing the power supply voltage V_{VPS} . Please make sure:

$$V_{VPS} \geq V_{LDAMAX} + 1V,$$

where V_{LDAMAX} is the maximum possible laser diode voltage.

Figure 18. Controller Internal Temperature vs. TMPO Voltage

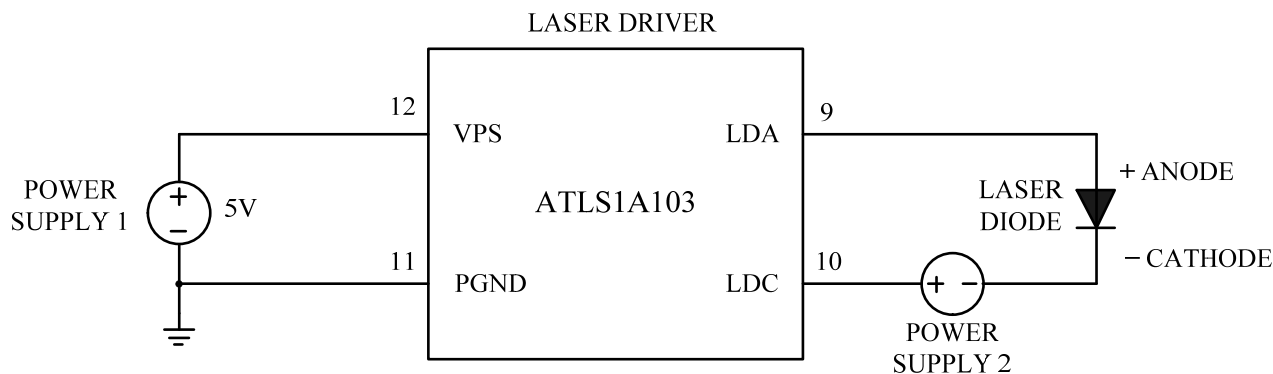

Figure 19. Driving High Voltage Laser Diodes

Driving High Voltage Laser Diodes

Some laser diodes have high forward voltage, such as 7V, while the laser driver ATLS1A103D has a maximum output voltage of 4V. This section tells a way to drive such laser diodes by using this laser driver.

The schematic is shown in Figure 19, where Power Supply 1 is the power supply for the laser driver, Power Supply 2 is for increasing the laser driver's maximum output voltage.

Please notice that the power on sequence has to be in this way: turn on Power Supply 1, turn on Power Supply 2, then

turn on the laser driver by driving SDN (Shutdown) pin to logic high.

The sequence for turning off the laser circuit is: turn off the SDN pin by pulling it down to the logic low, turn off Power Supply 1, then, turn off power supply 2.

To make sure the circuit works ok: turn on the laser, measure LDA voltage, it should be between 1V to 3V, at room temperature, the ideal LDA voltage is around 2V.

MECHANICAL DIMENSIONS AND MOUNTING

The ATLS1A103 comes in 2 packages: through hole mount and surface mount. The former is often called DIP (Dual In-line package) or D (short for DIP) package and has a part number: ATLS1A103D, and the latter is often called SMT (Surface Mount Technology) or SMD (Surface Mount Device) package and has a part number: ATLS1A103S. ATLS1A103DL comes with longer pins (4.0mm) than ATLS1A103D. See Figure 20, Figure 21, and Figure 22 for the dimensions.

Figure 20. Dimensions of the ATLS1A103D/ATLS1A103-PD

Figure 22. Dimensions of the ATLS1A103S

Figure 23 shows the feet print which is seen from the top side of the PCB; therefore, it is a “see through” view.

Figure 24 shows the view of the bottom side PCB footprint.

“Tent” (i.e. cover the entire via by the solder mask layer) all the vias under the controller, otherwise, the vias can be shorted by the bottom plate of the controller which is internally connected the ground.

Please notice that, in the recommended foot print for the DIP package, the holes for pin 2 to 6, and 8 to 12 have larger holes than needed for the pins. This arrangement will make it easier for removing the controller from the PCB, in case there is a rework needed. The two smaller holes, for pin 1 and 7, will hold the controller in the right position.

It is also recommended to use large copper fills for VPS, PGND, and the LDC pins, and other pins if possible, to decrease the thermal resistance between the module and the supporting PCB, to lower the module temperature.

Please be notice that the SMT version cannot be soldered by reflow oven. It must be soldered manually.

ORDERING INFORMATION

Table 3. Part Number

Part #	Description
ATLS1A103D	Controller in DIP package
ATLS1A103S	Controller in SMT package
ATLS1A103-PD	Controller with a pull-down resistor of 100k to the ground in SDN pin.

Warning: Both the surface mount and the through hole types of modules can only be soldered manually on the board by a solder iron of < 310°C (590°F), not go through a reflow oven process.

NOTE: The power supply may have overshoot, when happens, it may exceed the maximum allowed input voltage, 6V, of the controller and damage the controller permanently. To avoid this from happening, do the following:

1. Connect the controller solid well with the power supply before turning on the power.
2. Make sure that the power supply has sufficient output current. It is suggested that the power supply can supply 1.2 to 1.5 times the maximum current the controller requires.
3. When using a bench top power supply, set the current limit to >1.5 times higher than the maximum current the controller requires.
4. This laser driver can be evaluated by our evaluation board, [ATLS1A103DEV1.0](#).
